# 1. Introduction

## 1 pages

Triangulations, that is subdividing the plane (or a polygon) into triangles, are a popular topic in computational geometry — not only because of their connections to other problems but also due to their practical applications. They can be helpful as a preprocessing in other algorithms or as a tool in geometric proofs. One popular example is the artgallery problem . Another area where triangulations are widely used is mesh generation and approximation of complex geometric structures.

For different use cases the objectives for a triangulation vary. For example, the widely known Delaunay triangulation [2, Section 9.2] tends to avoid '"skinny'" triangles and is therefore useful for meshes. One can image many different properties to be optimized: Edge lengths, triangle area, angle, and degree in a vertex are some of them. Many have already been looked into, but for some of them no application is known by now — so they remain theoretical problems. In chapter 3 we will have a brief overview of different kinds of triangulations.

This thesis will focus on the MaxMin Length Triangulation (MMLT). Stated an open problem in 1991 [9], it has been proven to be NP-complete in 2012 [11]. However our assumption is that the hard instances are rare and that random instances can be solved in polynomial time on average. Therefore we provide an algorithmic idea in chapter 4 and its implementation in chapter 5.

Even though there seems to be no known application of MMLT yet, it is Greg's [18] preferred kind of triangulation.

# 2. Integer Programming

### 8 pages: ||||

#### glue text

#### Definition 2.1 ((Linear) Integer Program (IP))

An IP is a system of integer variables  $x \in \mathbb{Z}^n$  with a set of constraints on them and often an objective function  $c^T x$ . We consider only the case where the constraints are linear:  $Ax \leq b$  or  $Ax \geq b$ .

#### glue text

#### Problem 2.2 (IP in canonical form [22])

or

#### Theorem 2.3

Solving IPs is NP-hard.

#### **Proof:**

Even the special case where there is no objective function, only binary variables, and only equality constraints is NP-complete [16]. Therefore the more general problem is NP-hard.

#### 2.1. Vertex Cover

#### glue text

#### Definition 2.4 (Vertex Cover)

Given an undirected graph G = (V, E), a vertex cover  $V_{\text{cover}} \subseteq V$  for G is a vertex set such that every edge  $e \in E$  is incident to at least one vertex  $v \in V_{\text{cover}}$ :

$$\forall e \in E : \exists v \in V_{\text{cover}} : v \in e$$

#### glue text

#### Definition 2.5 (Minimal Vertex Cover)

A vertex cover  $V_{\text{cover}}$  for an undirected graph G = (V, E) is minimal if there is no vertex  $v \in V_{\text{cover}}$  such that  $V_{\text{cover}} \setminus \{v\}$  remains a vertex cover.

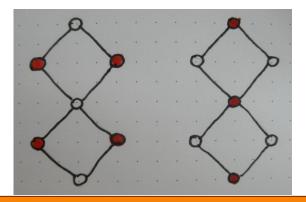

#### glue text

#### Definition 2.6 (Minimum Vertex Cover)

A vertex cover  $V_{\text{cover}}$  for an undirected graph G = (V, E) is minimum if there is no other vertex cover  $V'_{\text{cover}}$  for G which has fewer vertices:

$$\forall V'_{\text{cover}} \text{ vertex cover} : |V_{\text{cover}}| \leq |V'_{\text{cover}}|$$

#### glue text

# replace

Figure 2.1.: Example of minimal vs. minimum vertex cover

#### Problem 2.7 (IP Formulation of Minimum Vertex Cover)

minimize 
$$\sum_{v \in V} x_v$$
 subject to  $\forall \{v, w\} \in E : x_v + x_w \ge 1$  
$$\forall v \in V : x_v \in \{0, 1\}$$

#### glue text

#### Theorem 2.8

Vertex Cover is NP-complete. [16]

#### glue text

#### Definition 2.9 (Well-covered Graph)

An undirected graph G = (V, E) is well-covered iff every minimal vertex cover for G is also a minimum vertex cover for G. [23]

#### glue text

#### Theorem 2.10

In a well-covered graph, all minimal vertex covers have the same cardinality. [23]

# 2.2. Independent Set

#### glue text

#### Definition 2.11 (Independent Set (IS))

Given an undirected graph G = (V, E), an independent set  $V_{IS} \subseteq V$  is a vertex set such that no two vertices  $v, w \in V_{IS}$  are incident to the same edge  $\{v, w\} \in E$ :

$$\forall v \in V_{IS} : \forall \{v, w\} \in E : w \notin V_{IS}$$

#### glue text

#### Definition 2.12 (Maximal/Maximum Independent Set)

For an undirected graph G=(V,E), an independent set  $V_{IS}\subseteq V$  is maximal if there is no vertex  $v\in V\setminus V_{IS}$  such that  $V_{IS}\cup \{v\}$  remains an independent set. It is maximum if there is no independent set  $V'_{IS}$  with larger cardinality.

#### glue text

#### Theorem 2.13 (Independent Set and Vertex Cover)

For an undirected graph  $G=(V,E), V_{IS}\subseteq V$  is a maximum independent set iff  $V_{\text{cover}}=V\setminus V_{IS}$  is a minimum vertex cover.

# 2.3. Set Cover

#### evaluate if we really need set cover

#### Problem 2.18 (Minimum Weight Set Cover)

Given: A "universe" (set) of objects U, subsets  $S = \{S_i\}$  such that  $\bigcup_{S_i \in S} S_i = U$ ,

and a weight function  $c: S \to \mathbb{R}_+$ 

**Sought:** A set  $R \subseteq S$  which covers the universe, i.e.  $\bigcup_{S_i \in R} S_i = U$  and minimizes

 $\sum_{S_i \in R} c(S_i)$ 

Problem 2.18 is NP-hard [17] and the related decision problem was already one of the problems Karp has shown to be NP-complete [16].

# 3. Triangulations

4 pages

glue text

#### Definition 3.1 (Triangulation)

Given the complete undirected graph

$$K_{|V|}=(V,E=\{e=\{v,w\}:v,w\in V\wedge v\neq w\})$$

of a vertex set V and a set of conflicts  $X \subseteq \{\{e_i, e_j\} : e_i, e_j \in E \land e_i \neq e_j\}$ . A triangulation  $T(V, X) \subseteq E$  of V with respect to X is a maximum set of non-conflicting edges:

$$e_i \in T(V, X) \iff e_i \in E \land \forall e_j \in T(V, X) : \{e_i, e_j\} \notin C$$

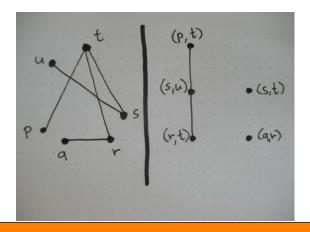

glue text

#### Definition 3.2 (Conflict Graph)

The conflict graph  $G_{\text{conf}}(E, X) = (E, X)$  for a set of edges E and conflicts  $X \subseteq \{\{e_i, e_j\} : e_i, e_j \in E \land e_i \neq e_j\}$  is an undirected graph with E as vertices and X as edges.

glue text

Theorem 3.3 (Equality of Triangulation and Maximum Independent Set) Every triangulation T(V, X) of a vertex set V with respect to conflicts X is a maximum independent set for the conflict graph  $G_{\text{conf}}(E, X)$  and vice versa. Hereby E are the edges of the complete undirected graph  $K_{|V|}$  for V.

replace

Figure 3.1.: Example of a conflict graph

Proof:
...
proof

#### Theorem 3.4

From theorem 3.3 and theorem 2.17 follows that finding the triangulation T(V, X) of a vertex set V with respect to conflicts X can be calculated in polynomial time.

glue text

#### Definition 3.5 (Triangulation with Forbidden Edges)

A triangulation with forbidden edges T(V, X, F) is a triangulation of the vertex set V with respect to conflicts X which does not contain any of the edges in F:

 $\forall e \in F : e \notin T(V, X, F)$ 

glue text

#### Theorem 3.6

The decision problem whether a triangulation with forbidden edges T(V, X, F) exists is NP-complete.

cite Lloyd: On Triangulations of a Set of Points in the Plane, triangulation existence problem

#### Definition 3.7 (Constrained Triangulation)

. . .

definition

# 3.1. Point Set Triangulations

glue text

#### Definition 3.8 (Planar Points)

A planar set of points or set of points in the plane P is a set of points with two coordinates:

$$P \subseteq \{p = (p_x, p_y) : p_x, p_y \in F\}$$

We do not make any assumptions on the coordinates besides F being a field, e.g. the real numbers  $\mathbb{R}$ . Furthermore, because P is a set, no duplicate points  $p=(p_x,p_y)\in P$  and  $p'=(p'_x,p'_y)\in P$  with  $p_x=p'_x$  and  $p_y=p'_y$  are allowed. Note however that we do not require the points in P to be in general position as that would forbid some interesting instances.

glue text

#### Definition 3.9 (Line Segments)

A line segment s = (p, q) is determined by its endpoints  $p, q \in P$  with P being a point set. For compatibility with other definitions, s is directed from p to q, i.e.  $(p, q) \neq (q, p)$  and contains all points "between" p and q:

$$m \in s \iff \exists a \in [0,1] : m = p + a \cdot (q - p)$$

#### glue text

#### Definition 3.10 (Crossing)

Two line segments  $s_i = (p_i, q_i)$  and  $s_j = (p_j, q_j)$  with different slope are *crossing*, if their intersection is not empty and not an endpoint, i.e.

$$s_i, s_j \ crossing \iff (p = s_i \cap s_j) \land (|s_i \cap s_j| = 1) \land (p \notin \{p_i, q_i, p_j, q_j\})$$

Two segments  $s_i$  and  $s_j$  are non-crossing if they are not crossing. A set S of segments is crossing if at least two segments  $s_i, s_j \in S$  are crossing. It is non-crossing if each pair  $s_i, s_j \in S$  is non-crossing.

#### glue text

#### Definition 3.11 (Overlapping Segments)

Given a point set P and a line segment s=(p,q) with  $p,q\in P$ . s is overlapping in P iff there is a point  $p'\in P$  which lies in its interior:

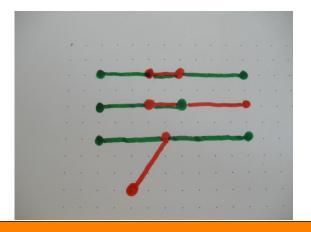

$$s \ overlapping \iff \exists p' \in P : (p' \in s) \land (p' \notin \{p,q\})$$

s is non-overlapping if it is not overlapping.

#### glue text

#### Definition 3.12 (Topological Representation)

A vertex set V(P) represents a point set P iff there is exactly one vertex  $v_p \in V(P)$  for each point  $p \in P$  and  $v_p$  can be identified by p and vice versa.

replace

Figure 3.2.: Examples of overlapping segments.

#### Definition 3.13 (Point Set Triangulation)

The triangulation T(P) of a point set P is a triangulation with forbidden edges T(P) = T(V, X, F) where the vertex set V = V(P) represents P, the conflicts X are all crossing segments and the forbidden edges F are the overlapping segments:

$$\{\{v_p, v_q\}, \{v_{p'}, v_{q'}\}\} \in X \iff (p, q), (p', q') \ crossing$$
  
 $\{v_p, v_q\} \in F \iff (p, q) \ overlapping$ 

For convenience we define  $s = (p, q) \equiv e = \{v_p, v_q\}$  such that  $s \in T(P) \iff e \in T(P)$ . For a slightly different yet equivalent definition of a point set triangulation see also [2, Section 9.1]. Note that for P in general position F is empty.

#### Theorem 3.14

A point set triangulation can be calculated in polynomial time.

- hint to edge flipping paper

notes

#### 3.4. Related Work

After class was over, Greg asked Mrs. Minerva if there are different kinds of triangulations. She replied that the problem of triangulating has kept researchers busy for over 100 years already [13] and that people have found different aspects in that a triangulation can be optimal.

The most famous class is the Delaunay triangulation [2, Section 9.2]. It forces every circumcircle of a triangle to be empty of other points and therefore maximizes the minimum angle [2, Theorem 9.9]. There is an edge flipping algorithm which calculates it in  $O(n \log n)$  expected time using O(n) space [2, Theorem 9.12].

There are several other triangulations which can be computed in polynomial time. Minimizing the maximum edge length in  $O(n^2)$  times was one of the first results [9]. The counterpart of a Delaunay triangulation, minimizing the maximum angle, takes  $O(n^2 \log n)$  time and O(n) space [3]. The same approach can also produce triangulations which maximize the minimum height of a triangle. Finally, the same reference shows also that minimizing the maximum slope and minimizing the maximum eccentricity can both be done in  $O(n^3)$  time and  $O(n^2)$  space. A triangulation which minimizes or maximizes the area of triangles can be computed in  $O(n^2 \log n)$  time with  $O(n^2)$  space. [24]

Other triangulations have been proven NP-hard or NP-complete. One of them is to minimize the edge length sum (also known as the minimum weight triangulation) which is NP-hard [21]. Maximizing the minimum edge length was stated an open problem [9] but 20 years later it has been shown that it is NP-complete [11]. The latter one remains NP-hard for polygons with holes and interior points [5] but can be solved in  $O(n^3)$  time for simple polygons and even in linear time for convex polygons [14].

# 4. MaxMin Length Triangulation

# 2 pages

During lunch, Greg thought about the different types of triangles Mrs. Minerva had told him about (chapter 3) and which ones he liked the most. On one hand he liked triangles with long edges, on the other hand Greg was very interested in NP-complete problems. Therefore he decided to find out more about MaxMin Length Triangulation (MMLT), which forces the shortest edge to be as long as possible and was proven NP-complete [11].

#### Problem 4.1 (MMLT)

Given: Set of points in the plane P and implicitly their induced segments  $S_P$  (see

??)

**Sought:** Triangulation  $T_{\text{opt}} \subseteq S_P$  of P which maximizes  $\min_{s \in T_{\text{opt}}} |s|$  with |s| being the

length of the segment s

When playing around with some small instances <sup>1</sup>, Greg discovered two properties of MMLTs. An optimal solution need not be unique as fig. 4.1 shows. Additionally fig. 4.2 is an example where an edge flip is necessary in a local optimum to gain global optimality. Therefore it is not always possible to retrieve an optimal MMLT solution by starting with an arbitrary triangulation and applying locally optimal edge flips.

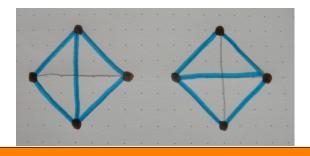

explain edge flips

#### Definition 4.2 (Edge Length Order)

Given a set of edges E representing a set of line segments S and two edges  $e_{s_i}, e_{s_j} \in E$  representing two line segments  $s_i, s_j \in S$ , respectively. Let |s| for  $s \in S$  be the segment length and  $s_i < s_j$  the lexicographical order of  $s_i, s_j \in S$ . The edge length order is defined as

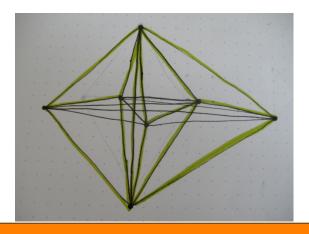

$$e_{s_i} < e_{s_j} \iff |s_i| < |s_j| \lor ((|s_i| = |s_j|) \land (s_i < s_j)).$$

<sup>&</sup>lt;sup>1</sup>Greg drew them on napkins in the cafeteria.

replace

Figure 4.1.: Example of different optimal solutions for the same point set.

replace

Figure 4.2.: Example of necessary locally non-optimal flips.

# Definition 4.3 (Edge Length Index)

Given a set of edges E representing a set of line segments S and an edge  $e \in E$ . The edge length index |e| is the index of e in E sorted by edge length order.

#### Problem 4.4 (MaxMin Edge Length Index Triangulation (MMELIT))

Given: Set of points in the plane P

Sought: Topological triangulation  $T_{\text{opt}} = (V, E)$  of P which maximizes the minimum

edge length index:  $\min_{e \in E} |e|$ .

#### Theorem 4.5

The optimal edge in a MMELIT solution is unique.

#### **Proof:**

. . .

proof

#### Theorem 4.6

Every optimal MMELIT solution is an optimal MMLT solution.

#### **Proof:**

. . .

proof

#### IP:

- maximize min. edge index
- no conflicting edges
- for every edge: either edge or crossing edge picked
- $n^2$  variables,  $O(n^4)$  restrictions

notes

## 4.1. Separators

He tried to identify the good, the bad, and the ugly edges. Bad are clearly all short edges as they can worsen the MMLT solution. Step by step, Greg found the set of all segments which were shorter than a certain threshold and named them the "short segments".

#### Definition 4.7 (Short Edges)

Given a set of edges E representing a set of line segments S. Short edges within E are all edges with an edge length index smaller than a certain threshold:

$$E_{\text{short}}(P, \ell) := \{ e \in E : |e| < \ell \}$$

The next observation Greg made is that there were some long segments which cross the short segments. Greg called them "separators" as they separate the endpoints of short segments. When the shortest segment which is part of the MMLT solution has separators, it can (under certain conditions) be replaced by a longer segment to improve the solution. Therefore separators are the good segments.

#### Definition 4.8 (Separators)

Given a set of edges E representing a set of line segments S and a set of conflicts  $C \subseteq E^2$ . The set of separators  $E_{\text{sep}}(E,C,e)$  for an edge  $e \in E$  are all edges that improve the MMELIT solution, i.e. all in C with e conflicting edges which have a higher edge length index:

$$E_{\text{sep}}(E, C, e) := \{e_{\text{sep}} \in E : |e| < |e_{\text{sep}}| \land \{e, e_{\text{sep}}\} \in C\}$$

Finally, there are the ugly segments which are short but have no separators such that they can not be replaced  $^2$ . A special case are segments which do not cross at all — for example those on the convex hull. The ugliest segment is the shortest of all ugly segments  $e_{\text{nose}}$ .

<sup>&</sup>lt;sup>2</sup>...which is not their fault!

#### Definition 4.9 (Shortest Non-separable Edge)

Given a set of edges E representing a set of line segments S and a set of conflicts  $C \subseteq E^2$ . The shortest non-separable edge  $e_{\text{nose}}$  is the edge with the smallest edge length index which has no separators:

$$e_{\text{nose}} := \mathop{\arg\min}_{e \in E: E_{\text{sep}}(E,C,e) = \emptyset} |e|$$

Greg pities the ugly segments because nobody likes them even though they are not bad. So he tries to find something where they are good at. When the boy thinks back to the art class, he remembers that a triangulation  $T \subseteq S_P$  of a point set P is a maximum set of non-crossing segments (??). So any segment  $s \in S_P$  that is not crossed by another segment  $s_{\times} \in T$  has to be part of T itself. A similar property applies to the ugly segments in a MMELIT: Every segment  $s \in S_P$  with no separators is either part of an optimal MMELIT solution  $T_{\text{opt}}$  or crosses a shorter (or equal length) segment  $s_{\times} \in T_{\text{opt}}$ .

#### Theorem 4.10 (upper bound)

Given a set of edges E representing a set of line segments S and a set of conflicts  $C \subseteq E^2$ . Let  $T_{\text{opt}}$  be an optimal MMELIT solution for P. Every segment s without separators is an upper bound for  $T_{\text{opt}}$ :

$$\forall s \in S_P, \ E_{\text{sep}}(P, s) = \emptyset : \min_{s_{\min} \in T_{\text{opt}}} |s_{\min}| \le |s|$$

which is equivalent to

$$\forall s \in S_P : \neg \exists E_{\text{sep}} \in S_P : |s| < |E_{\text{sep}}| \land s, E_{\text{sep}} \ crossing \implies \min_{s_{\min} \in T_{\text{opt}}} |s_{\min}| \le |s|$$

#### **Proof:**

Assume

$$\exists s \in S_P, \ E_{\text{sep}}(P, s) = \emptyset : \min_{s_{\min} \in T_{\text{opt}}} |s_{\min}| > |s|.$$

This implies  $s \notin T_{\text{opt}}$  and

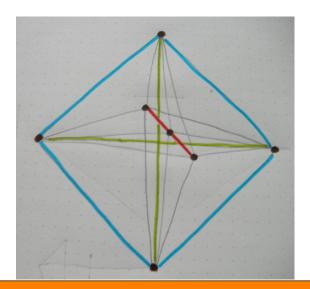

$$\forall s' \in S_P : |s'| \le |s| \implies s' \notin T_{\text{opt}}.$$

With  $E_{\text{sep}}(P, s) = \emptyset$  it follows that

$$\forall s_{\times} \in S_P : s, s_{\times} \ crossing \implies s_{\times} \notin T_{\text{opt}}.$$

This means that for  $T_{\text{opt}}$  to be a triangulation s has to be in  $T_{\text{opt}}$ —which is a contradiction.

Unfortunately, Greg soon found an example where the ugly segments did not help: fig. 4.3. In this instance, there are short segments which have conflicting (crossing) separators. This forces one short segment to be part of the optimal triangulation as only one of the separators can be selected. Therefore the upper bound for an optimal MMLT solution in theorem 4.10 is not tight.

replace

Figure 4.3.: Example where the upper bound from theorem 4.10 is not tight. One of the short segments (red) is part of an optimal MMLT solution because their separators (green) cross. Thus the shortest segment in the solution is shorter than the shortest one of all segments without separators (blue).

Greg remembered that he had met conflicting segments in fig. 4.2 already. By conflicting he meant that the separator  $E_{\text{sep}}$  of a segment s either crossed any segment  $s_{\times}$  shorter than s or the separator which replaced  $s_{\times}$ .

#### Definition 4.11 (Conflicting Segments)

Given planar point set P and its induced segments  $S_P$ . The (potentially) conflicting segments for a segment  $s \in S_P$  are:

$$S_{\text{conf}}(P, s) := \bigcup_{s_{\times} \in E_{\text{short}}(|s|)} s_{\times} \cup E_{\text{sep}}(s_{\times})$$

Greg immediately started to rethink his earlier understanding of ugly segment. His opinion was that short segments with only conflicting separators were as ugly as those with no separators at all. The latter ones are even a special case of the first group. So he changed theorem 4.10 to take conflicting separators into account. A segment may be part of an optimal MMLT solution because all of its separators interfere with other segments. The following theorem assumes knowledge of the optimal triangulation, so conflicting segments can only be found iteratively after the triangulation has already be calculated for shorter segments. However, we will see how conflicts can be formulated independently later on.

#### Theorem 4.12 (tight upper bound)

Given a point set P and its induced segments  $S_P$ . Let  $T_{\text{opt}}$  be an optimal MMLT solution for P. Every segment s without non-conflicting separators is an upper bound for  $T_{\text{opt}}$ :

$$E'_{\text{sep}}(P, s) := \{ E_{\text{sep}} \in E_{\text{sep}}(P, s) : E_{\text{sep}} \cup (T_{\text{opt}} \cap S_{\text{conf}}(P, s)) \text{ non-crossing} \}$$

$$\forall s \in S_P : E'_{\text{sep}}(P, s) = \emptyset \implies \min_{s_{\min} \in T_{\text{opt}}} |s_{\min}| \le |s|$$

can we get  $T_{\text{opt}}$  out of the bound?

#### **Proof:**

This proof is very similar to the proof of theorem 4.10. Assume

$$\exists s \in S_P : E'_{\text{sep}}(P, s) = \emptyset \land \min_{s_{\min} \in T_{\text{opt}}} |s_{\min}| > |s|.$$

That implies  $s \notin T_{\text{opt}}$  and

$$\forall s' \in S_P : |s'| \le |s| \implies s' \notin T_{\text{opt}}.$$

If  $E_{\text{sep}}(P,s) = \emptyset$  itself, according to theorem 4.10 it holds that

$$\min_{s_{\min} \in T_{\text{opt}}} |s_{\min}| \le |s|$$

which is a contradiction.

Now assume  $E_{\text{sep}}(P,s) \neq \emptyset$ . The following holds:

$$\forall E_{\text{sep}} \in E_{\text{sep}}(P, s) : E_{\text{sep}} \cup (T_{\text{opt}} \cap S_{\text{conf}}(P, s)) \text{ crossing.}$$

With  $T_{\text{opt}}$  being a triangulation this implies

$$\forall E_{\text{sep}} \in E_{\text{sep}}(P, s) : E_{\text{sep}} \notin T_{\text{opt}}.$$

Therefore

$$\forall s_c \in S_P, \ s, s_c \ crossing : s_c \notin T_{\text{opt}}.$$

That means that s has to be in  $T_{\mathrm{opt}}$  – which is a contradiction.

#### Theorem 4.13 (tightness)

The bound of theorem 4.12 is tight. That is, let T be a feasible MMLT solution and  $s_{\min} = \underset{s \in T}{\operatorname{arg \, min}} |s|$  with no non-conflicting separators:

$$\neg \exists E_{\text{sep}} \in E_{\text{sep}}(s_{\min}) : E_{\text{sep}} \cup (T_{\text{opt}} \cap S_{\text{conf}}(s_{\min})) \text{ non-crossing}$$

Then T is optimal.

**Proof:** 

Assume not optimal, compare optimal, prove not optimal

#### 4.2. Set Cover

As a consequence of theorem 4.12 with theorem 4.13, we introduce the following smaller (in terms of input and output size) problem Non-Conflicting Separators (NCS). For  $S = \{s \in S_P : |s| \leq |e_{\text{nose}}|\}$  an optimal solution  $S_{\text{opt}}$  for NCS has the same shortest segment as an optimal MMLT solution  $T_{\text{opt}}$ :

$$\min_{s \in S_{\text{opt}}} |s| = \min_{s \in T_{\text{opt}}} |s|$$

#### Problem 4.14 (NCS)

Set of short segments S and their separators  $E_{\text{sep}}$ . Given:

**Sought:** Set of non-crossing segments  $S_{\text{opt}} \subseteq S \cup \bigcup_{s \in S} E_{\text{sep}}(s)$  which contains for

each segment  $s \in S$  either the segment itself or at least one separator

 $E_{\text{sep}} \in E_{\text{sep}}(s)$  and maximizes  $\min_{s \in S_{\text{opt}}} |s|$ .

The NCS problem can be modeled as a weighted set cover problem. Therefore it is also NP-hard.

#### IP:

- maximize min. edge index
- no conflicting edges
- for every short edge: either edge or separator picked
- worst case: n^2 variables, O(n^4) restrictions
- random points: O(n) variables,  $< O(n^3)$  restrictions?

notes

#### Problem 4.15

Given: Set of short segments S and their separators  $E_{\text{sep}}$ .

Sought: (here comes the reduction

# 4.3. Algorithm

Now that Greg knew all about MMLT he could start developing algorithm 4.1. It consists of three main components: Constructing the partial intersection graph, running a binary search over the short segments and solving the smaller NCS problem in each step, and using the resulting segments in a constrained triangulation.

mention segment index and introduce notation  $S_P[i]$ 

## Algorithmus 4.1: MMLT algorithm

```
Input: Planar point set P
    Output: An optimal MMLT
 {f 1} solution for P
 2 Generate the induced segments S_P for P
 3 Find the shortest non-separable segment e_{\text{nose}} and calculate intersections for
    E_{\text{short}}(|e_{\text{nose}}|) and their separators
 4 Set the lower bound lb = 0
 5 Set the upper bound ub such that S_P[\mathsf{ub}] = e_{\text{nose}}
 6 Set last = \emptyset
 \mathbf{7} \ \mathbf{while} \ \mathsf{lb} < \mathsf{ub} \ \mathbf{do}
         Set mid = \left\lceil \frac{lb + ub}{2} \right\rceil
 8
         Find optimal NCS solution S_{\text{opt}} for E_{\text{short}}(P, |S_P[\mathsf{ub}|)]
 9
         without using any segment from E_{\text{short}}(P, |S_P[\mathsf{mid}|))
         if there is a solution S_{\text{opt}} then
10
              Set last = S_{\text{opt}}
11
              Maximize |\mathsf{b}| = \min_{s \in S_{\mathrm{opt}}} |s|
12
              \mathbf{if}\ \mathsf{lb} > \mathsf{ub}\ \mathbf{then}
13
                | lb = ub
14
         else
15
              \mathbf{if}\ \mathsf{lb} < \mathsf{mid}\ \mathbf{then}
16
                Set \mathsf{ub} = \mathsf{mid} - 1
17
              else
18
                    Set ub = lb
```

20 return constrained triangulation  $T_{\text{opt}}$  with last as constraints

## 4.4. Intersection Graph

For a point set P with n points in the plane the induced segments (see ??) have  $\Theta(n^4)$  intersections. [19] Thus calculating the intersection graph takes  $\Omega(n^4)$  time.

- link to sweep line algorithm
- sweep line takes  $O(n^4 \log n)$  time => brute force is faster
- adjacency list, because sparse (experiment? proof?)

#### notes

```
Algorithmus 4.2: intersection algorithm
```

# 5. Implementation

## 2 pages

To get his algorithm implemented Greg asked Winfried Hellmann, a friend of him who studied computer science. He instantly agreed and started to plan the structure. There were two main components: Geometry and Optimization.

To let the program run close to the hardware layer (which usually leads to fast execution times), the code was written in C++. First attempts to use Python instead (for the sake of clarity and better readability) stumbled over the non-readiness of the CGAL bindings and the lack of good alternatives.

## 5.1. Geometry

The geometry part consists now of the basics like number, point, and segment types, data structures for triangulation and convex hull, and the intersection algorithm. For most of it Winfried made extensive use of CGAL, which will be introduced in section 5.1.1.

#### 5.1.1. CGAL

CGAL [4] is an Open Source library (mainly) for computational geometry written in C++. It includes most of the common algorithms in the field and also offers efficient data structures. Through the use of C++ templates it is flexible and extendable: For example it is common to adjust the underlying number types to the application.

#### 5.1.2. Kernel

A kernel in CGAL is something like a computational geometry operating system: It holds the basic type definitions like numbers, points, lines, and line segments. Basic operations such as intersection, angle calculations, or comparisons are also part of it.

In our application we use the built-in Exact\_predicates\_inexact\_constructions\_kernel<sup>1</sup> [10], which uses double as a number type and is not capable of constructing new objects from existing ones accurately. Both properties lead to faster execution time yet do not produce wrong results in our case.

On top of the CGAL kernel there are two modifications: One is for printing points and segments without the need to use streams, the other one to output them to SVG (see also sections 5.3.2 and 5.3.6). Additionally segments are indexed by length and have the information whether they overlap with other segments attached to them.

<sup>&</sup>lt;sup>1</sup>Thanks to Michael Hemmer for making me aware that I should use it!

#### 5.1.3. Triangulation

CGAL brings along a constrained triangulation already [7] which triangulates a point set with respect to a given mandatory set of (non-crossing) edges. For this application the class was extended to be drawable to SVG and to find the shortest edge which is part of the triangulation.

#### 5.1.4. Convex Hull

This class directly calls the convex\_hull\_2 function of CGAL [8] which itself defaults to the algorithm of Akl & Toussaint [1]. The only extension is that the class serves as container which holds the output points and contains a function to find the shortest segment within.

For the algorithm this class is not necessary as its bound is worse than the one of the SAT solution. It is left in the implementation though as a measure of quality for the other bound.

#### 5.1.5. Intersection Graph

- crossing segments as conflict edges
- adjacency list
- maybe later replaced by boost graph?

## 5.2. Optimization

The optimization part itself consists mainly of data structures for SAT problems and solutions, an interface for SAT solvers and the solvers themselves (currently only CPLEX).

Only segment indices and intersections are passed to the SAT problem. This is because geometry does not influence the problem, but only topology. Also it is easier that way to keep track of which segments take part in the restrictions.

## 5.2.1. SAT problem

This class serves two purposes: To grant an interface to the relevant data for the SAT (i.e. segments and intersections) and to set the short segment range.

#### 5.2.2. SAT solution

The SAT solution class mainly just stores the segment indices derived from solving the SAT problem — which can be none if no feasible solution is found. Additionally it offers methods for drawing short segments and separators and for finding the shortest segment of the solution.

## 5.2.3. SAT solver

To unify the way solving the SAT problem is done, there are three interfaces: The base SAT solver and two derived interfaces for decision and optimization problems. They all share methods for adding forbidden segments, intersection and separation restrictions and for running the actual solving. Furthermore there is a method for binding short segments to the objective function for optimization problems.

#### 5.2.4. CPLEX

IBM ILOG CPLEX [15] is a commercial optimization suite written in C. It contains a standalone tool for solving optimization problems and also includes libraries for being used in other programs or even other programming languages. According to [20] CPLEX is one of the two fastest MILP solvers.

In our application we use the Concert API for C++ [6] to access CPLEX. It allows for adding variables and restrictions to a model, extracting them to more efficient data structures and then running several solving algorithms on it.

#### 5.3. Remains

And then there is the rest: A controller class for the whole algorithm which combines all the other components and utility classes for reading input files, debug output and assertions, test case generation, and drawing certain states of the algorithm to SVG.

#### 5.3.1. Boost

https://www.boost.org/

- boost spirit for JSON parsing
- maybe later: boost datetime and format for logging, boost graph for intersection graph and SVG output

#### 5.3.2. Qt

https://qt-project.org/

- event-based programming framework
- logging
- SVG output
- simplified build system and IDE

#### 5.3.3. JSON Parser

- JSON spirit (url!)
- built-in JSON of Qt 5 has bug => no STL/boost/CGAL compatibility

## 5.3.4. Logger

- conditional output of different information  $% \left( 1\right) =\left( 1\right) +\left( 1$
- used for evaluation of algorithm output

## 5.3.5. Point Generator

- CGAL point generator
- evenly distributed points in (unit) square

## 5.3.6. SVG Painter

- conditional algorithm state output
- example?

# 6. Results

3 pages
some very nice graphs

## 6.1. Technical Details

- Intel® Core<br/>™ 2 Duo CPU E6850
- 2 GB RAM
- CGAL version

# 6.2. Segment Lengths

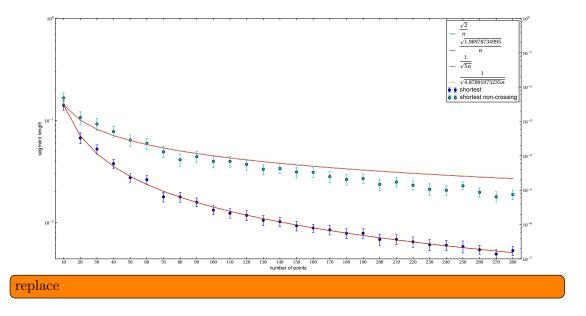

Figure 6.1.: Comparison of segment lengths

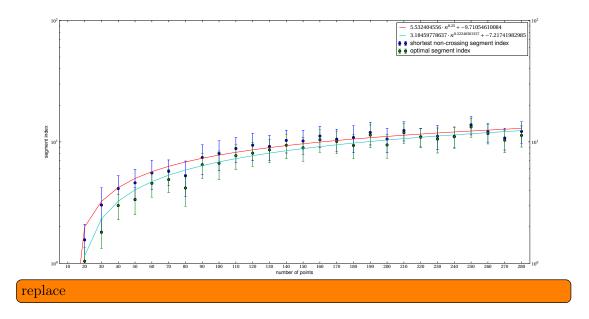

Figure 6.2.: Comparison of segment indices

# 6.3. Execution Time

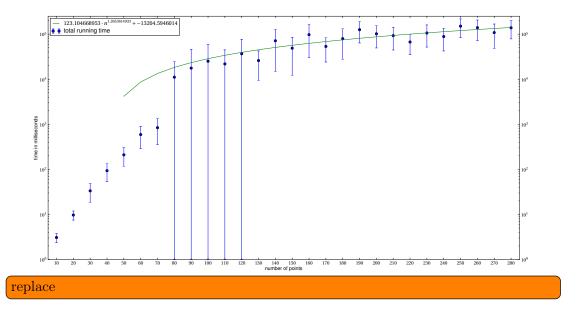

Figure 6.3.: Total execution time

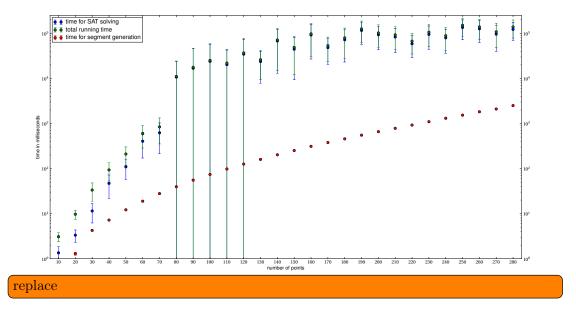

Figure 6.4.: Comparison of execution times

# 6.4. Aborted instances

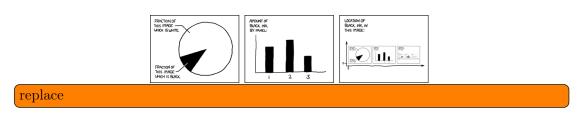

Figure 6.5.: Number of aborted instances

# 7. Conclusion

## 2 pages

With the MaxMin Length Triangulation (MMLT) algorithm at hand Greg made his way to world domination.

be conclusive
